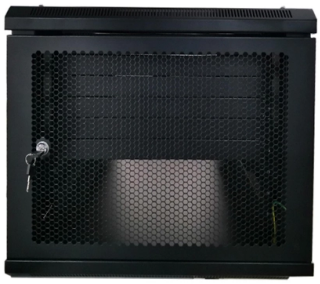
Differences and similarities between single-mode and multimode optical fibers



Overview

How do you choose between single mode and multimode fiber? Compare their differences in core size, light source, bandwidth, transmission distance, and cost to identify the right application.

Key Takeaways

Single-mode fibers are optimized for long-distance, high-bandwidth transmission with a narrow core, while multimode fibers are designed for shorter distances and cost-effective, high-speed local networks. Core Diameter and Light PropagationSingle-mode fiber (SMF) has a small core diameter of about 8–10 µm, allowing only a single light mode to propagate, which minimizes modal dispersion and maintains signal integrity over long distances. Multimode fiber (MMF) has a larger core, typically 50 µm or 62.

5 µm, enabling multiple light modes to travel simultaneously. This larger core makes MMF easier to couple with light sources but introduces modal dispersion, limiting its effective transmission distance. Bandwidth and Transmission DistanceSingle-mode fibers support higher bandwidths and can transmit signals over tens to hundreds of kilometers without significant signal degradation, making them ideal for telecom backbones and long-haul networks.

Multimode fibers are suitable for shorter distances, typically within data centers or campus networks, with bandwidth limited by modal dispersion. Effective modal bandwidth (EMB) for MMF is usually expressed in MHz·km at 850 nm. Light Sources and WavelengthsSMF typically uses laser light sources at 1310 nm or 1550 nm, which provide precise, focused signals for long-distance transmission.

MM

F commonly uses LEDs or VCSELs at 850 nm, with some legacy applications at 1300 nm. The choice of light source affects cost, coupling efficiency, and network performance. Cost and HandlingSingle-mode fibers are more expensive due to precise manufacturing requirements and the need for laser-based transceivers.

They are also more challenging to terminate and handle. Multimode fibers are more cost-effective for short-range applications, easier to install, and compatible with less expensive transceivers. ApplicationsSingle-mode fiber: Long-haul telecom, metro networks, 5G backbones, and high-bandwidth enterprise networks.

Multimode fiber: Data centers, LANs, short-distance high-speed connections, and budget-sensitive deployments. Single-mode is preferred for long-distance, high-performance networks, while multimode is ideal for short-range, economical deployments.
