Fiber optic cable interfaces of the three major telecom operators

Overview

Comparing the Fiber Strategies of the Big Three U.S. Mobile OperatorsTom Leins examines the respective fiber strategies of the “Big Three” U.S. mobile oper.

Key Takeaways

AT&T, Verizon, and T-Mobile primarily use GPON and FTTH-based passive optical networks for their fiber deployments, with optical line terminals (OLTs) at central offices connecting to optical network units (ONUs) or terminals (ONTs) at customer premises. AT&T Fiber InterfacesAT&T has deployed fiber-to-the-home (FTTH) networks using GPON (Gigabit Passive Optical Network) technology, which allows a single fiber from the central office to serve multiple homes via passive splitters. Their network supports multi-gigabit download and upload speeds, and the company has also formed a joint venture, Gigapower, to expand fiber access beyond its traditional footprint.

AT&T's interfaces typically include OLT equipment at the central office, passive splitters in the field, and ONTs at customer premises. Verizon Fiber InterfacesVerizon's fiber network, branded as Fios, also relies on GPON-based FTTH architecture. The network uses OLTs at Verizon's central offices, which connect through passive splitters to ONTs at homes and businesses.

Verizon's fiber supports high-speed symmetrical connections and is designed for both residential and business services. The network is scalable, allowing upgrades to 10G-PON or higher as demand grows.

Mobile Fiber InterfacesT-Mobile, historically a mobile operator, has been expanding its fiber footprint to support backhaul for 5G and fixed broadband services. While T-Mobile's fiber strategy is less extensive than AT&T or Verizon, it also uses GPON and FTTH technologies for last-mile connections in select markets.

T-

Mobile leverages fiber primarily for network convergence, connecting mobile towers and providing high-speed broadband to residential and enterprise customers.

Common Fiber Network Architecture

All three operators use a passive optical network (PON) topology, which is point-to-multipoint. Key components include: Optical Line Terminal (OLT): Located at the service provider's central office, managing multiple downstream and upstream connections. Passive Splitters: Split a single fiber into multiple fibers to serve several customers without active electronics.

Optical Network Units (ONUs) / Optical Network Terminals (ONTs): Installed at customer premises to terminate the fiber and provide Ethernet or Wi-Fi connectivity. Amplifiers (optional): Used in longer runs to maintain signal strength. This architecture reduces the amount of fiber and central office equipment compared to point-to-point connections, while supporting high-speed broadband and scalability for future upgrades such as 10G-PON or NG-PON2.

SummaryAT&T: FTTH with GPON, multi-gigabit speeds, Gigapower JV expansion, OLT → splitter → ONT. Verizon: Fios FTTH, GPON, scalable to 10G-PON, OLT → splitter → ONT.

T-

Mobile: Expanding FTTH/GPON for 5G backhaul and broadband, OLT → splitter → ONT. All three operators rely on passive optical networks for last-mile delivery, ensuring efficient, scalable, and high-speed fiber connectivity for residential and business customers.
