Optical modules plugged into the switch

Overview

Pluggable Optical Transceivers Pluggable optical transceivers are standalone modules that go into the switch or NIC and convert electrical to optical signa.

Key Takeaways

Optical modules connect to switches via hot-pluggable electrical sockets on the switch, with fiber optic cables linking the module to the network.

Physical Connection

Optical modules, such as SFP, QSFP, or CFP transceivers, are designed to be hot-pluggable, meaning they can be inserted or removed from a switch without powering it down. They typically plug into a front-panel socket or an on-board socket on the switch. The module's electrical interface mates with the switch's internal circuitry, allowing data to flow between the switch's backplane and the optical module.

Electrical Interface

The electrical side of the optical module carries digital signals between the switch and the module. Early modules used analog NRZ interfaces, but modern modules use retimed digital interfaces such as the Common Electrical Interface (CEI), which standardizes high-speed data transmission. This interface ensures that the switch can send and receive data at the required bandwidth without signal degradation.

Optical Interface

On the network side, the optical module has a fiber optic interface. A fiber optic cable is connected to the module, transmitting data as light pulses. The module converts electrical signals from the switch into optical signals for transmission over fiber, and vice versa for incoming signals.

This allows the switch to communicate over long distances at high speeds. Integration with Switch ArchitectureInside the switch, the module interfaces with the switch fabric or backplane, which routes data to the appropriate output ports. In some optical switches, the module may participate in optical-electrical-optical (OEO) conversion, where incoming light is converted to electrical signals for processing and then back to light for output.

In all-optical switches, the module may directly interface with the optical switching fabric, keeping the signal in light form throughout.

Summary

In essence, optical modules are connected to switches through standardized electrical sockets, while fiber optic cables link the module to the network. This setup allows high-speed, flexible, and scalable data communication, supporting both traditional OEO and modern all-optical switching architectures.
