

Power Control Relay Protection

Overview

Primary Protection Relays | ABBABB's Relion family of protection and control relays for primary distribution offers a wide range of products for protection.

Key Takeaways

Relay protection settings ensure safe, reliable, and coordinated operation of electrical power systems by defining current, time, and fault thresholds for protective relays. Key Relay Settings1. Plug Setting Multiplier (PSM) PSM represents how many times the actual current exceeds the relay's pickup current.

It is crucial for inverse definite minimum time (IDMT) relays, determining the operating speed based on the fault current. A higher PSM results in faster tripping, and settings must comply with IEC 60255-151 standards for overcurrent relays. 2.

Time Setting Multiplier (TSM) TSM scales the base operating time derived from the relay's characteristic curve. It allows coordination between upstream and downstream relays, ensuring backup protection.

Lower TS

M values produce faster trips, while higher values delay upstream relay operation to avoid unnecessary tripping. 3. Overload Setting (OL) OL protects equipment from thermal damage due to prolonged overcurrent.

It is typically set based on the rated current of the protected device and the thermal capacity of conductors or transformers. 4. Earth Leakage / Earth Fault Setting (EL) EL detects ground faults by monitoring current imbalance.

Proper E

L settings prevent equipment damage and ensure personnel safety while avoiding nuisance trips. 5. Multiplying Factor (MF) MF, also called the metering or scaling factor, adjusts relay readings to match actual system currents, especially when using current transformers (CTs) with specific ratios.

Relay Protection Calculations

Accurate relay settings require fault level and current calculations: Current and Voltage Sensing: Determine maximum load, minimum fault currents, and voltage levels to ensure relay sensitivity and reliability. Fault Level Calculations: Analyze single line-to-ground, line-to-line, and three-phase faults using symmetrical and asymmetrical fault analysis tools. These calculations ensure relays operate selectively, isolating only the faulted section while maintaining system stability.

Coordination and Validation

Relay coordination involves grading time and current settings so that downstream relays trip first, and upstream relays provide backup. Validation includes testing relay operation under simulated fault conditions to confirm proper response and compliance with standards.

Practical Considerations

Use numerical or multifunctional relays for modern HV/MV substations to combine protection, metering, and control in one device.

Ensure C

T ratios and burden are compatible with relay inputs.

Follow IEC and IEE

E standards for relay performance, coordination, and safety. Properly configured relay protection enhances system reliability, prevents equipment damage, and ensures personnel safety in high- and medium-voltage networks.
