Relay protection fault tripping

Overview

The static and microprocessor relay systems generally have more elaborate logic involved in the tripping decision, particularly in the area of transient blocking during external fault clearing. Static systems require more careful treatment of input circuits, i. This system integrates protection logic with breaker control functions. Essential. Engineering use: Relays are used on feeders, transformers, buses, motors, generators, and transmission lines to protect equipment and improve system reliability. What controls it: Relay performance depends on the protected zone, CT/PT inputs, pickup settings, time delay, breaker clearing time, trip. A protective relay is an intelligent electrical device designed to detect faults in power systems and initiate corrective actions such as tripping a circuit breaker. In theory, they respond to abnormal current, voltage, frequency, or impedance conditions and isolate faulty sections of the power system. Note that all generators- the power sources – have been disconnected.
