Key Takeaways

In a secondary distribution box (subpanel), the neutral is connected to the neutral bus bar but must remain separate from the ground; it is not bonded to ground except at the main service panel. Neutral in a Secondary Distribution BoxA secondary distribution box, also known as a subpanel, receives power from the main distribution panel or transformer and distributes it to branch circuits within a building or facility. The neutral conductor provides a return path for current from the loads back to the source, ensuring balanced operation of the AC system.

Separation of Neutral and Ground

According to electrical standards such as the NEC, neutral and ground must remain separate in subpanels. Bonding neutral to ground is only allowed at the main service panel or first service disconnect. If neutral and ground are connected in a subpanel, return current could flow through grounding conductors and metal enclosures, creating shock and fire hazards.

Therefore, in a secondary distribution box: The neutral bus bar is connected to the incoming neutral from the main panel or transformer secondary. The ground bus bar is connected to the building's grounding system (ground rods or grounding electrode) and to equipment grounding conductors. Neutral and ground are not bonded within the subpanel.

Connection to Transformers

In low-voltage secondary networks, the neutral is typically derived from the transformer secondary winding. For example, in a 480Y/277V system, the neutral is the center point of the transformer's secondary winding and is grounded at the transformer or main panel. The secondary distribution box then distributes phase and neutral to branch circuits while maintaining the separation of neutral and ground.

Summary

Yes, the secondary distribution box is connected to neutral via the neutral bus bar. No, the neutral is not bonded to ground in the subpanel; bonding occurs only at the main service panel. This separation ensures safety, proper current return paths, and compliance with electrical codes.

This configuration is standard for residential, commercial, and industrial installations to maintain safe and reliable power distribution.
