What are the two types of relay protection

Overview

Protective Relays: Types, Working Principle & UsesProtective relay coordination is the process of setting relays so the device closest to the fault operate.

Key Takeaways

The two main types of relay protection operation are instantaneous operation and time-delay operation.

Instantaneous Relay Operation

Instantaneous relays operate without any intentional time delay, responding almost immediately to abnormal conditions such as overcurrent or short circuits. Their operating time typically ranges from 1/2 to 3 cycles of the power frequency, depending on the magnitude of the fault current. These relays are used in situations where rapid disconnection is critical, such as in high-speed fault clearing zones to prevent cascading failures.

The pickup value, which determines the minimum current required to trigger the relay, can be independently set to suit specific protection requirements.

Time-

Delay Relay OperationTime-delay relays operate with a predefined delay that is inversely proportional to the magnitude of the fault current. Higher fault currents cause faster operation, while lower currents result in a longer delay. This type of operation is widely used in coordinated protection schemes, allowing upstream and downstream relays to operate selectively and minimize unnecessary disconnections.

The delay can be adjusted using a time-dial setting, which shifts the operating characteristic to match system coordination requirements.

Summary

Instantaneous operation: Immediate response, critical for fast fault isolation, no intentional delay. Time-delay operation: Delayed response, allows coordination with other relays, delay inversely proportional to fault magnitude. Both types are often combined in a single relay device, allowing flexible protection strategies for different zones and equipment in a power system.
